

Knowledge Graph	Graph Structure	Memory Role	Storage Content	Advantages	Limitations
 <p>Entity Extraction</p> <p>Entity: Stomachache, Active Attribution: Symptom Relation: Status</p>	<p>Entity: Stomachache, Active Attribution: Symptom Relation: Status</p> <p>Entity Extraction → Triples → Knowledge Graph</p> 	<p>Semantic Memory</p> <p>Stores factual knowledge.</p>	<p>Stores objective facts & conceptual relations. Structure is a network of (head entity, relation, tail entity) triples.</p>	<ul style="list-style-type: none"> ✓ Explicit relations, high interpretability ✓ Supports complex reasoning ✓ Easy to integrate external structured knowledge 	<ul style="list-style-type: none"> ✗ High construction & maintenance cost ✗ Struggle with fuzzy or unstructured information ✗ Poor at dynamic updates: make real-time updates complex and costly
 <p>Event Extraction</p> <p>Events with timestamps</p>	<p>Event Extraction → Event snapshots → Time slicing → Temporal Graph</p> 	<p>Episodic Memory Short-Term Memory</p> <p>Captures time sequences and transient events.</p>	<p>A set of nodes and hyperedges, where each hyperedge connects an arbitrary subset of nodes (≥ 2). Represented as an incidence matrix or bipartite graph.</p>	<ul style="list-style-type: none"> ✓ Native representation of n-ary relations: naturally model an event involving multiple participants ✓ Efficient associative retrieval 	<ul style="list-style-type: none"> ✗ Many graph algorithms are costly to run on hypergraph structures ✗ Requires careful design to map problems to hyperedges
 <p>Identify N-ary Relation Groups</p> <p>high-order dependencies</p>	<p>Identify N-ary Relation Groups → Hyperedge Construction → Hyperedges → Hypergraph</p> 	<p>Associative Memory</p> <p>Connects multiple entities implicitly.</p>	<p>Nodes represent events, tasks, or concepts; directed edges denote parent-child relationships. Organizes specific events, task steps, or knowledge into hierarchies.</p>	<ul style="list-style-type: none"> ✓ Intuitive layout ✓ Efficient top-down retrieval strategy ✓ Clear abstraction levels: summarizes information at different granularities 	<ul style="list-style-type: none"> ✗ Rigid structure struggles to represent overlapped or non-hierarchical relationships ✗ Parent-node vulnerability
 <p>Manageable contents</p>	<p>Manageable contents → Cluster → Hierarchical contents → Summarize → Hierarchical Graph</p> 	<p>Procedural Memory, Episodic Memory</p> <p>Encodes routines and organizes event snapshots.</p>	<p>Nodes represent events or entity states at specific times; often incorporates timestamps as node/edge attributes or uses time-sliced graph snapshots.</p>	<ul style="list-style-type: none"> ✓ Explicit temporal modeling: timestamps ✓ Tracks evolution: model how entities, relationships, or knowledge states change over time 	<ul style="list-style-type: none"> ✗ Storage and computational overhead ✗ Temporal granularity dilemma: hard to retrieve the right time for events ✗ Complex query processing over time
 <p>Facts</p> <p>Working experience</p>	<p>Facts → Knowledge component Working experience → Working component</p> <p>Router → Hybrid Graph</p> 	<p>Semantic Memory Episodic Memory Working Memory</p> <p>Integrates facts, experiences, and active processing.</p>	<p>Integrates multiple above graph structures (e.g., knowledge triples, dialogue sequences) via techniques like GNNs for joint representation & reasoning</p>	<ul style="list-style-type: none"> ✓ Integrate multi-source, heterogeneous memories ✓ Leverage strong representational power of GNNs 	<ul style="list-style-type: none"> ✗ Complex system design, requiring substantial training data ✗ Potential noise in information fusion
